

## Abstract: Queuing the Wrong U

Just as there are many different types of uncertainty, there are many different types of models. The best technique for quantifying and communicating uncertainty will depend on the nature of that uncertainty: is it mere imprecision in a well-defined number (as with the square-root of two), intractability (as when we know how to compute the answer, but have not yet been able to carry out the calculation), indeterminacy (as when there is no well-defined target about which to be imprecise) or other. The relevance of UQ to a decision maker or scientist will also depend on the type of quantitative model that is considered: is the model intended to explain, or to forecast, or to provide a quantitative analysis of the past?

When a perfect model is available, many of these distinctions collapse. In practice, attempting to quantify one type of uncertainty via a model which may not even display that kind of uncertainty is a nonsense. One must be careful not to confuse the diversity of our models for the uncertainty in our future. Or a well-defined probability forecast for what the next model simulation will report, with a probability forecast for the world. How is UQ to recognize the line between sensitivity analysis and probability forecasting? These questions will be addressed in the context of climate science, and more broadly that of science in support of decision making. The ways and means of UQ are shown to vary with type of model considered, the extent to which that model class is deemed adequate for purpose in a specific application, and whether or not the relevant dominant uncertainty (known from the science, but perhaps absent from the models) has been considered. Uncertainty Quantification may prove to be a very wide field, extending well beyond the bounds of the probability calculus.

# Distinguishing Types of Uncertainty

There are many different types of uncertainty.

Best practice requires UQ communicate the RDU (the dominant uncertainty relevant to the question at hand) **not** merely the easiest U to quantify!

Imprecision: There is a well defined value, it is merely unknown:

**314<sup>th</sup> digit of the  $\sqrt{2}$**

Intractability: The target may be well-defined, but using/determining it would prevent completion of the required calculations.

**Height of the Andes in a GCM**

Indeterminacy: There is no true value of be uncertain of.

**“The radius” of the Earth (as it not a sphere!)**

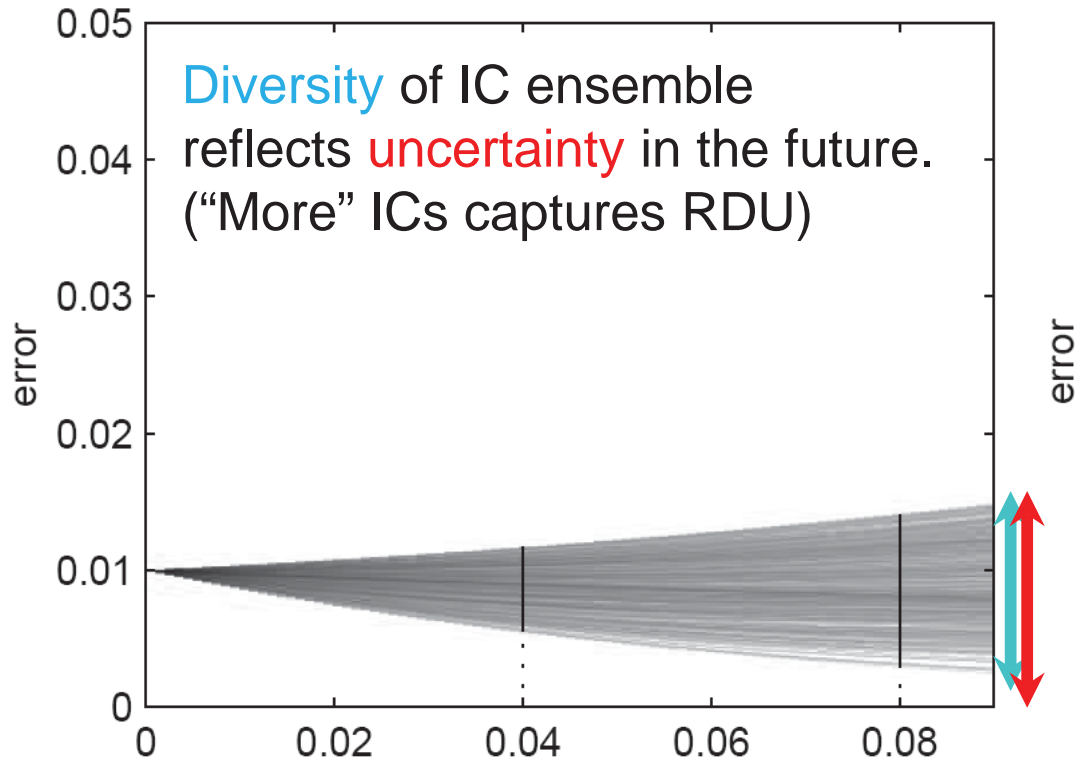

**The value of Newton’s gravitational constant G**

**To be of value in application UQ must move well beyond “imprecision”**

# Relevant Dominant Uncertainty

– Initial Condition Uncertainty  
(RDU is in IC)

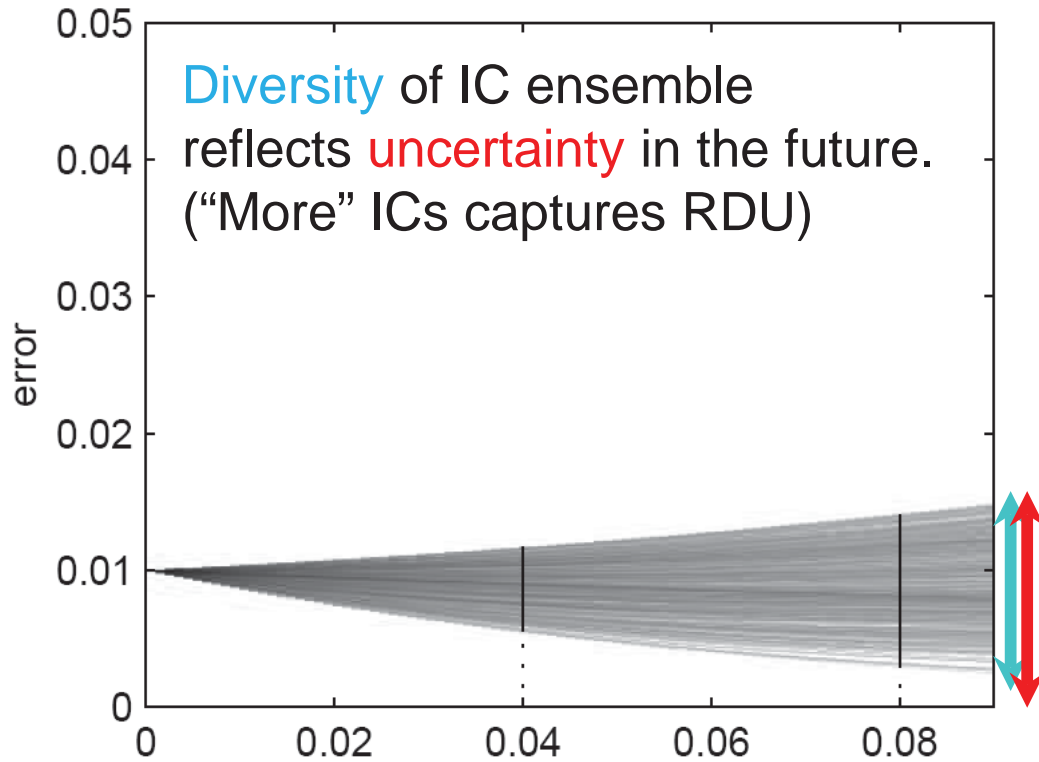

[D Orrell, LA Smith, T Palmer & J Barkmeijer \(2001\) Model Error in Weather Forecasting, Nonlinear Processes in Geophysics 8: 357-371.](#)

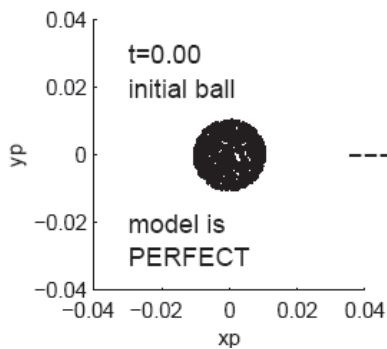

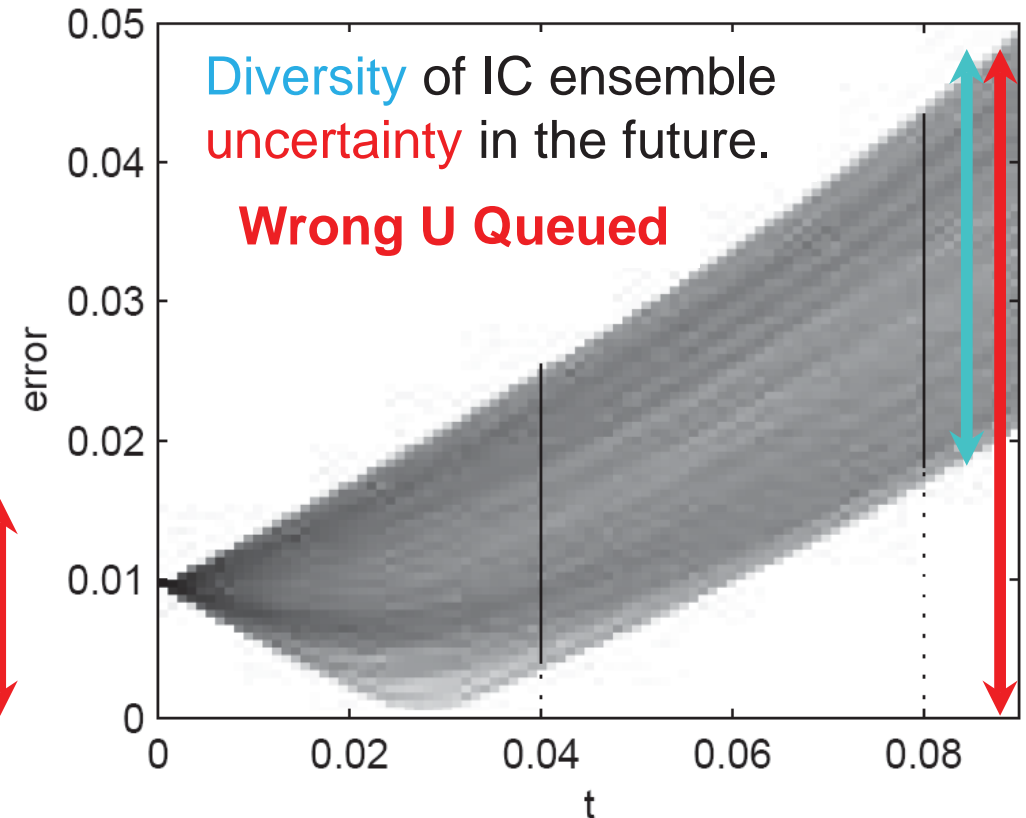

# Relevant Dominant Uncertainty

Initial Condition Uncertainty  
(RDU is in IC)

Structural Uncertainty  
(RDU is Model Inadequacy)

**D Orrell, LA Smith, T Palmer & J Barkmeijer (2001) Model Error in Weather Forecasting, Nonlinear Processes in Geophysics 8: 357-371.**

# The Galton Board

Each pellet has a 50/50 chance of going to the right (left) of each nail.

A mathematical result which is easier to match if you pour the shot in all at the same time...

But would any randomness remain if we knew exactly where each pellet started?

# The NAG Board

Not A Galton Board (2000)

Constructed for the

150<sup>th</sup> Birthday of the RMS

A given golf ball does **not** have a 50/50 chance of going to the right (left) of the next nail.

LA Smith (2007) Chaos A Very Short Introduction. OUP.

# Quantifying Uncertainty in the Initial Condition

In the NAG board, UQ due to IC uncertainty corresponds to considering a collection (ensemble) of golf balls...

IC UQ via ensembles informs us of uncertainty **within** our model!

If ICU is not the RDU, then this is merely a sensitivity analysis of the model, and need not quantify the uncertainty in our future.

The uncertainty in the next golf ball is quantified...

# Model Diversity does not $Q$ the relevant $U$

Ensembles inform us of uncertainty growth within our model(s)!

But **reality** is not a golf ball...

... **reality** is a red rubber ball.

What exactly does the distribution of 1024 golf balls tell us about where the one (and only) red rubber ball falls?

While we never see similar initial states, we can still learn from our mistakes!(in this weather-like case)

# NAG Weather and the Forecast-Outcome Archive

# Quantifying Uncertainty in the Initial Condition

In the NAG board, UQ due to IC uncertainty corresponds to considering a collection (ensemble) of golf balls...

The uncertainty in the next golf ball is quantified, but there comes a point where better quantifying that uncertainty does not better quantify the uncertainty most relevant to the target: the red ball.

# Science can anticipate RDU surprises beyond model-land

Interpreting even **weather-like** distributions is a challenge!

J Bröcker & LA Smith (2008) [From Ensemble Forecasts to Predictive Distribution Functions](#)  
*Tellus A* 60(4): 663 D

**Scientific speculation can help:**  
rubber balls will bounce more,  
will carry less angular  
momentum, will...  
These scientific insights can  
qualitatively inform the use of  
the quantitative golf ball  
distributions.

# Science can anticipate RDU surprises beyond model-land

Climate predictions require extrapolating out of the observed golf ball-rubber ball archive: into the known-to-be-different (?perhaps still fluid?) unknown.

The best we can hope for is sensible consistency **in distribution** between our models (“the details do not matter”).

**Scientific insight/speculation can anticipate “Big Surprises” (things our models cannot do)**

# Probabilistic Forecasts: IPCC Sixty-Forty Rule

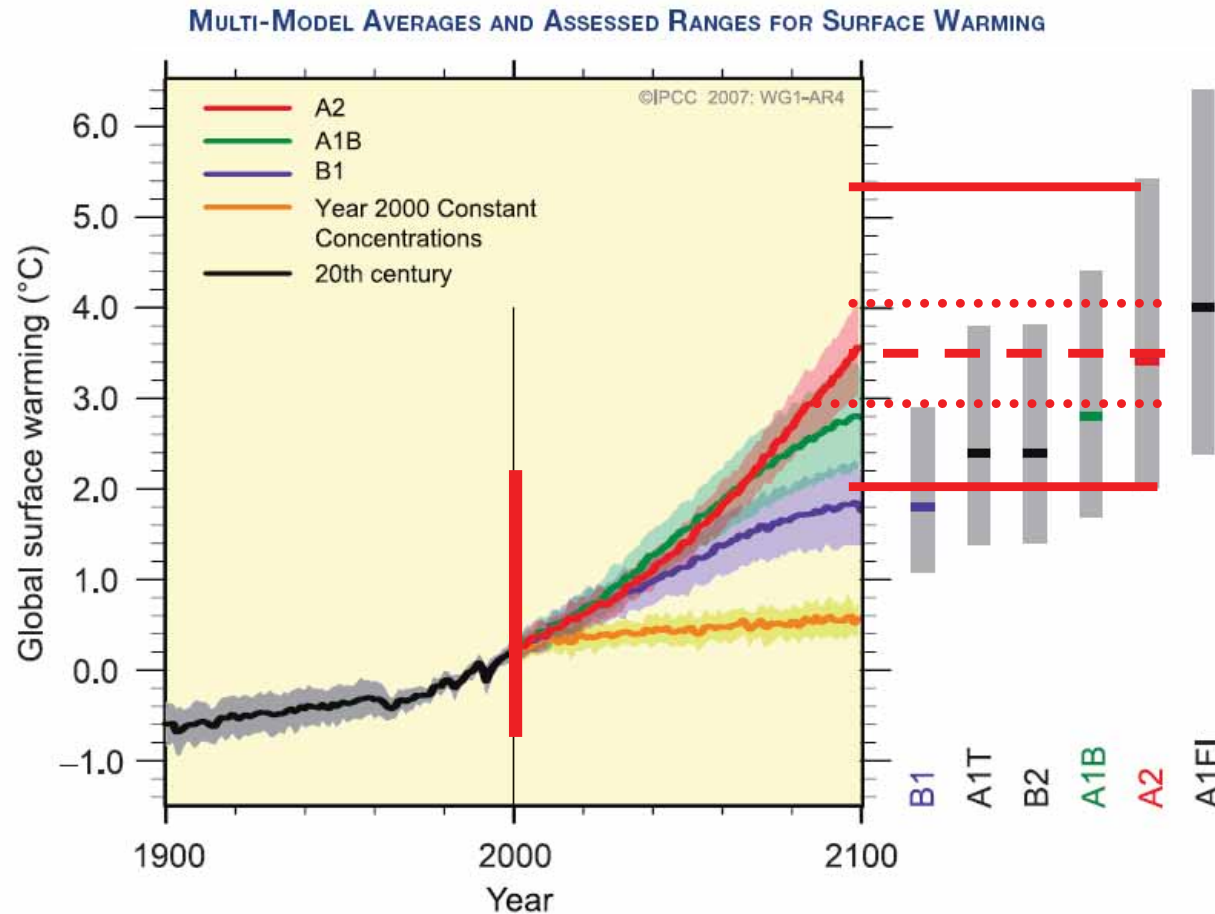

Figure SPM.5. Solid lines are multi-model global averages of surface warming (relative to 1980–1999) for the scenarios A2, A1B and B1, shown as continuations of the 20th century simulations. Shading denotes the  $\pm 1$  standard deviation range of individual model annual averages. The orange line is for the experiment where concentrations were held constant at year 2000 values. The grey bars at right indicate the best estimate (solid line within each bar) and the likely range assessed for the six SRES marker scenarios. The assessment of the best estimate and likely ranges in the grey bars includes the AOGCMs in the left part of the figure, as well as results from a hierarchy of independent models and observational constraints. (Figures 10.4 and 10.29)

The conditional forecasts (projections) are the grey bars (right); they differ from the ensemble distributions left and centre.

Of course, an adequately parameterised process might significantly shift the range. Discussions of “broadening” imply confidence the RDU will not shift in the location.

*Do we have that confidence Globally? Regionally?*

**The IPCC rejects the claim that diversity of ensembles directly reflects our uncertainty in GMT.**

# How important are different sources of uncertainty?

The value of qualitative insight is at risk of being discarded in favour of quantitative mis-information...

- Varies, but typically no single source dominates.

...if we have Queued the Wrong U here!

Uncertainties in winter precipitation changes for the 2080s relative to 1961-90, at a 25km box in SE England

# State-of-the-art GCMs share deficiencies due to technology

## Science is more than simulations

When does  
"Sit and Think" trump  
"Simulate and Count"?

Example: When we  
know moist air must go  
over or around in (and  
only in) the real world!

If our models cannot reproduce today's driving meteorological phenomena, can we expect them to get second order feedbacks "well enough"?

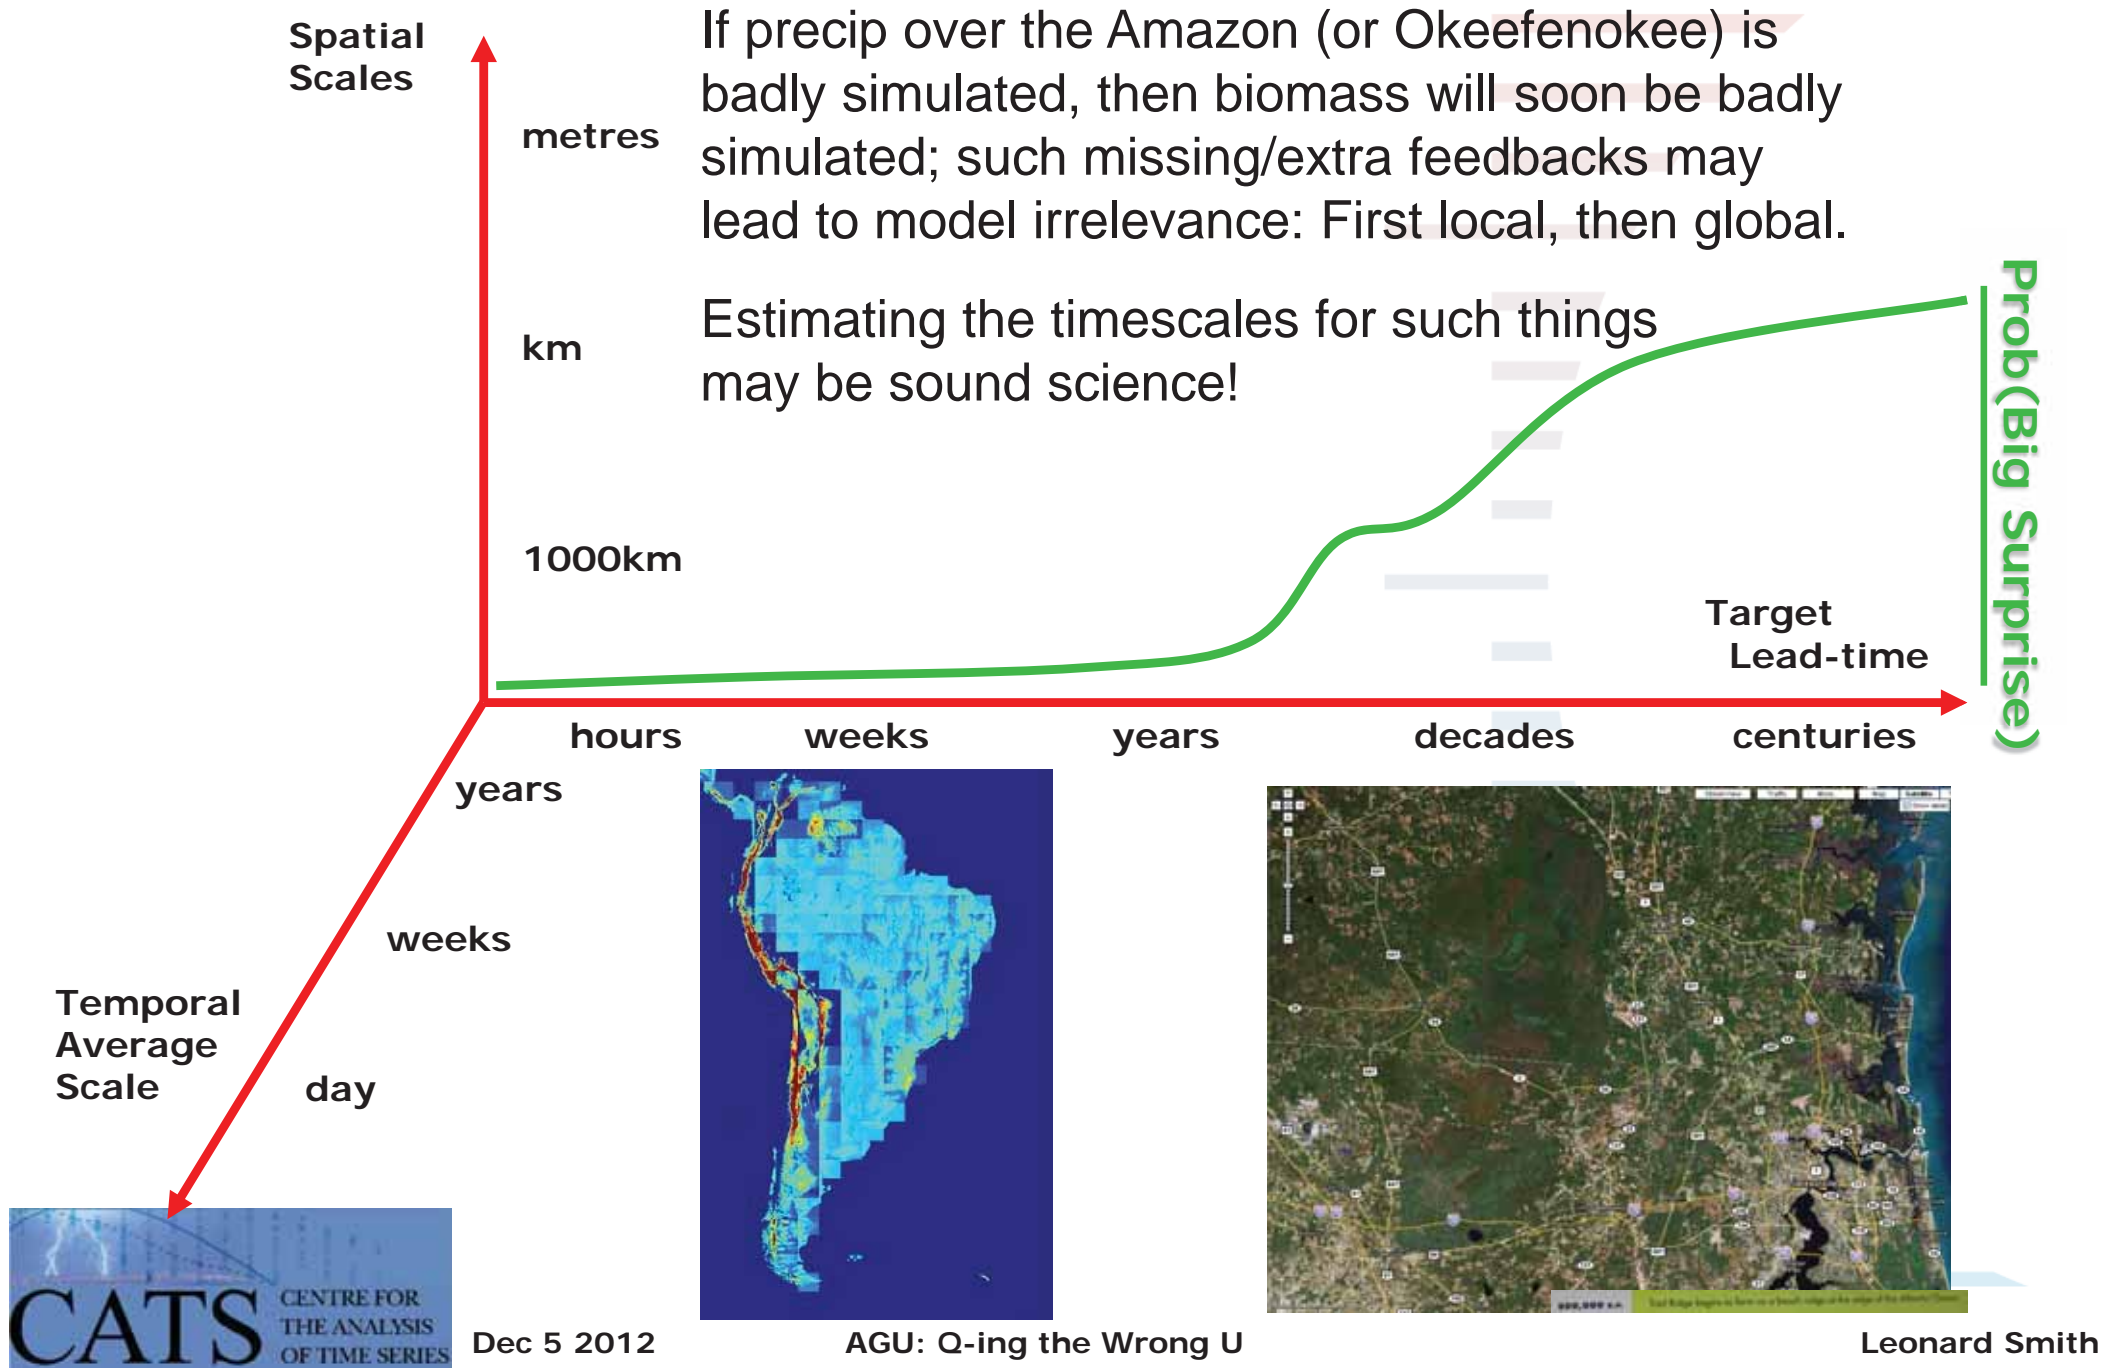

**At what lead times** do inadequacies in downstream flow (or precipitation) result in feedbacks with beyond local impacts? alter extremes? &c?

Science can estimate Prob(Big Surprise) as a function of lead time.

Missing 2km tall walls of rock!

# Model-based probability forecasts are incomplete without a quantitative measure of the likelihood of model irrelevance.

A genuine expert can always foretell a thing that is 500 years away easier than he can a thing that's only 500 seconds off.

- *A Connecticut Yankee in King Arthur's Court*

## What is a “Big Surprise”?

Big Surprises arise when something our simulation models cannot mimic turns out to have important implications for us.

Often we can identify cases where we are “leaking probability” when a fraction of our model runs explore conditions which we know they cannot simulate realistically. (Science can warn of “known unknowns” even when the corresponding futures remains unknown)

Big Surprises invalidate (not update) model-based probability forecasts changing the  $I$  in  $P(x|I)$ . (Arguably “Bayes” does not apply: this is not a question of probability theory.)

A genuine expert can always foretell a thing that is 500 years away easier than he can a thing that's only 500 seconds off.

- *A Connecticut Yankee in King Arthur's Court*

## Convergent Probabilities

In weather forecasts we can see the lead-time when our models become misinformative, but in climate forecasting we are in the dark.

If our models agreed (in distribution) why would we have more confidence?

Arguably only when the next U in the UQ queue can be argued small in theory: that is when all significant RDUs have been well quantified **and we no longer *expect* our probabilities to be evolving.**

## And if the best available model is not adequate for purpose

Accept (for a moment) that **Model Inadequacy** may make probability forecasting irrelevant in just the same way that **chaos** made the RMS/least-squares error of point forecasts irrelevant.

When the best model is not adequate for quantitative prediction or a RDU has not been quantified:  
What is the role of quantitative modelling & simulation in decision support? In explanation?

How can we better extract insight and information from big models and ensemble forecasts without taking them too seriously?

How do we do UQ in this case?

Might this lead to better decision making?

## Queuing the Right Uncertainty

*When in doubt, distrusting the indications, or inferences from them (duly considered on purely scientific principles, and checked by experience), the words “Uncertain,” or “Doubtful,” may be used, without hesitation.*  
Fitzroy, 1862

Best practice requires UQ communicate the RDU (the dominant uncertainty relevant to the question at hand), **not** the easiest uncertainty to quantify!

Conditioning on “the evidence considered” (rather than all the available evidence) will mislead decision makers and risk the credibility of science-based policy when an RDU is known not to have been “considered”.

**To be of value in application UQ must move well beyond “imprecision”.**

Where models disagree (in distribution), one must communicate the probability all available models are misinformative. Similarly when they agree!

What are the alternatives to using science to quantify the Prob(Big Surprise)?  
Are there not dangers to the credibility of science when it is suppressed?

Request Summary:

**Selecting your UK location first**

This page is intended for novice users of the UI who know what location they are interested in. This page should be used as follows:

**Step 1:** Click on a point on the map (or type in the latitude/longitude coordinates and click "Select").  
**Step 2:** Select a data source of interest from the list that appears on the right.  
**Step 3:** Select the variable you are interested in and click the "Next" button.

You can search by place name or postcode using the box on the right-hand side. Note that clicking a result re-centres and zooms the map to the new location but does not make a selection.

Selections on this page are restricted in that only a single location may be selected. Weather Generator simulations and Marine Model Simulations are not available from this start point.

[Read about starting your request by making spatial selections in the UI Manual](#)

**Search place name or postcode to re-centre map:**  
 Search Clear

Postcode: OX1 1DW

**Select by Latitude / Longitude by:**  
 Latitude: 52.0018  
 Longitude: -0.1044

**Step 2: Select a data source:**  
 At your chosen location, there is data for following data sources (clicking an option will highlight the selected location on the map adjacent):

- UK Probabilistic Projections of Climate Change over Land for the 25km Grid Box with the ID: 1551
- UK Probabilistic Projections of Climate Change over Land for the Administrative Region: East of England
- UK Probabilistic Projections of Climate Change over Land for the River Basin: Anglian

**Step 3: Select a variable:**  
 Please choose one of the following variables:

**Funded by:** defra, UK CLIMATE PROJECTIONS, Department for Environment and Heritage, The Scottish Government, Met Office, UK Climate Impacts Programme

**Provided by:** Met Office

Service hosted at: Science & Technology Facilities Council, Rutherford Appleton Laboratory.

# What is the aim of Climate Modelling?

It would be interesting to trace how the idea that climate models could provide quantitative insight came about.

Weather models are simplified climate models: you need not turn on ocean currents in the first few days, or ice in the first few weeks, or forest in the first few years...

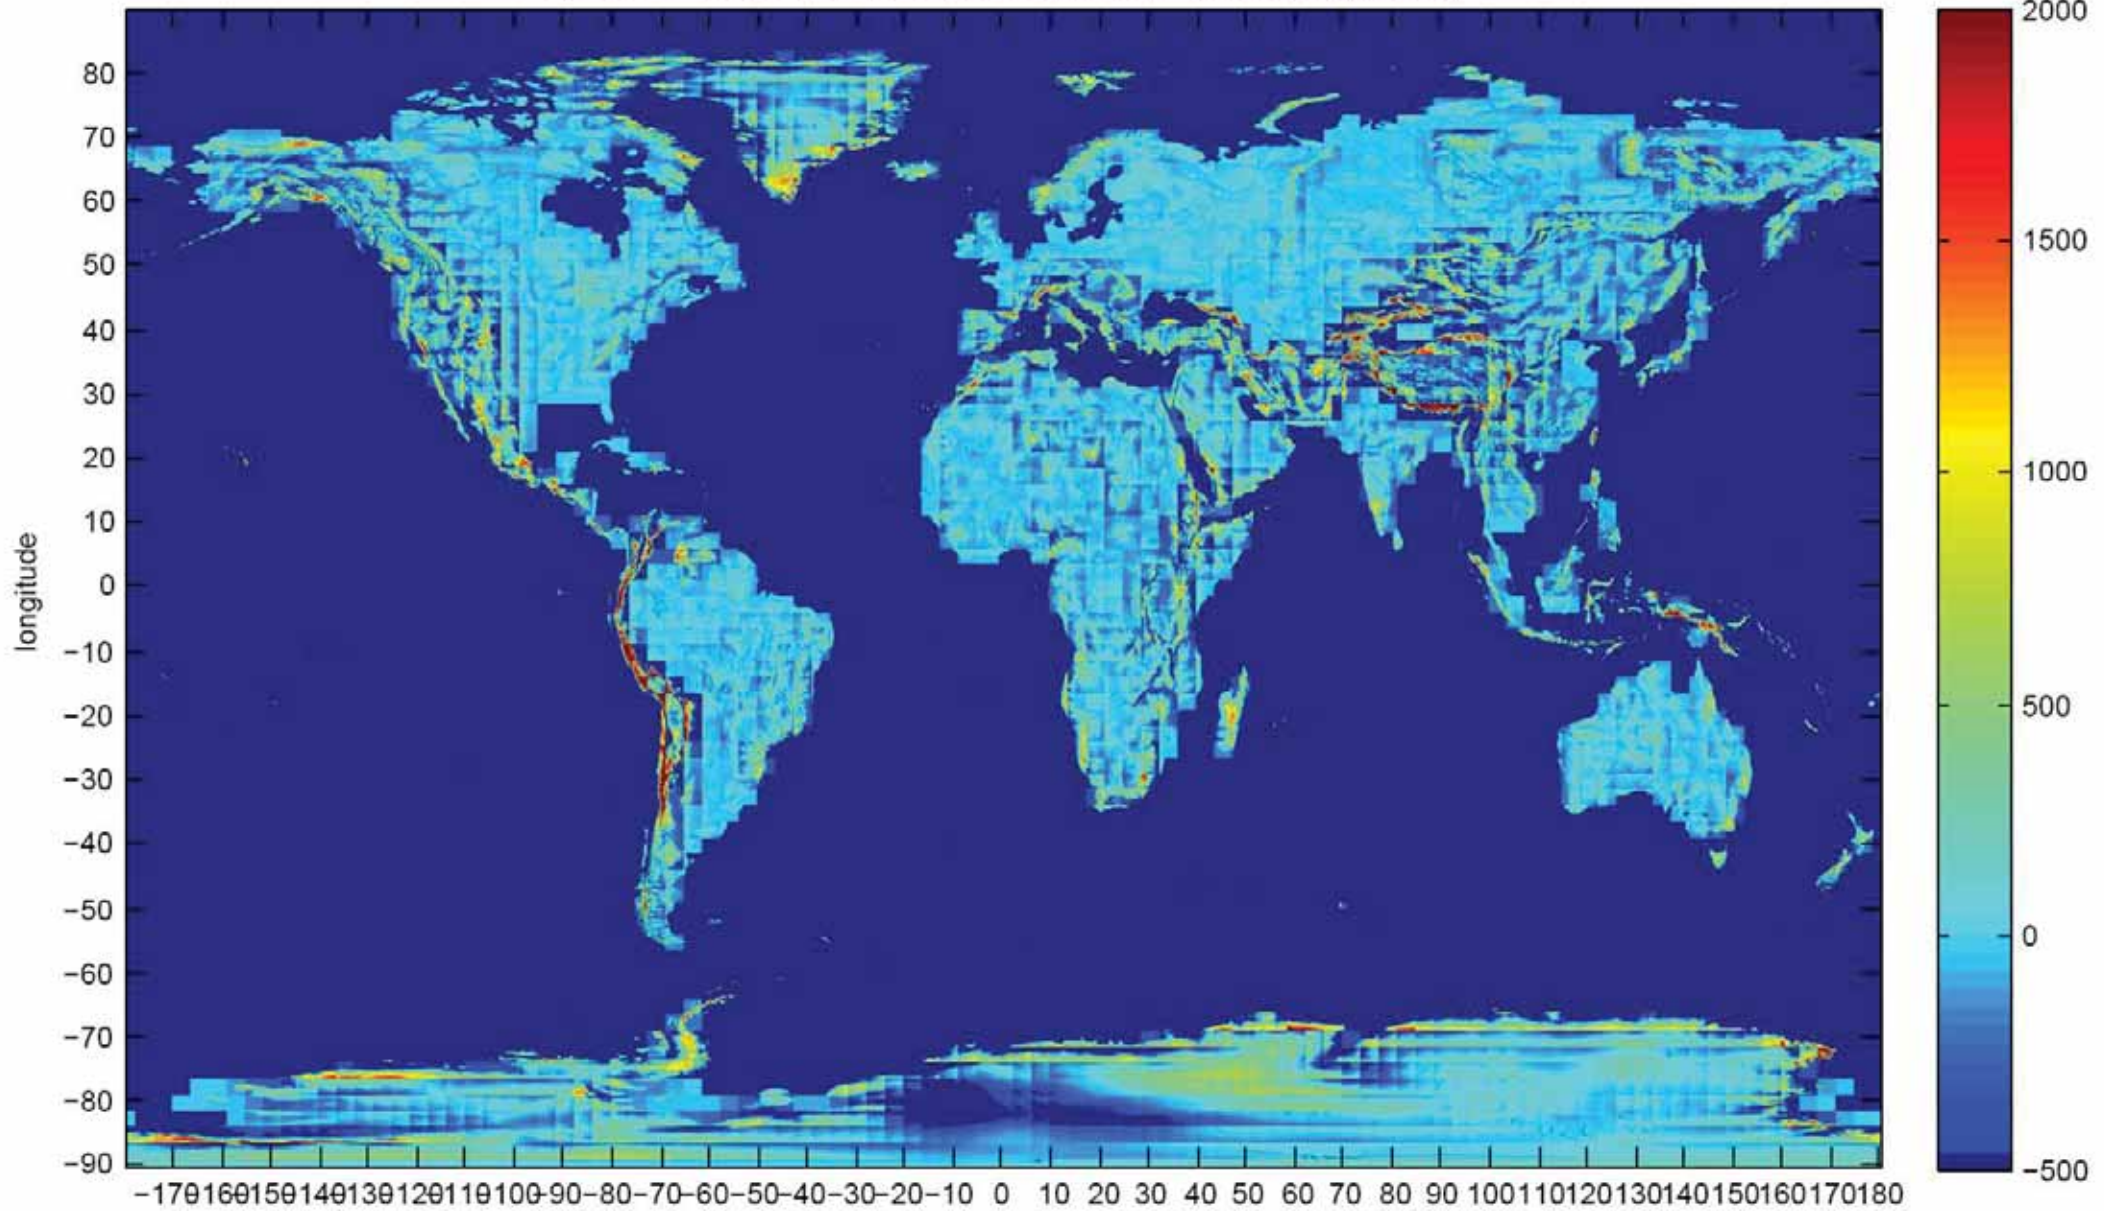

But climate models must run faster than real-time, and so are simplified in implementation: do we have the technology to run high fidelity climate models?

*Why do we hide behind clouds when we cannot realistically simulate rock?*

# The basic insight here is not new

**When in doubt, distrusting the indications, or inferences from them (duly considered on purely scientific principles, and checked by experience), the words “*Uncertain,*” or “*Doubtful,*” may be used, without hesitation.**  
**Fitzroy, 1862**

Dr. Platzman

I may add to this another point mentioned by Dr. Charney, a somewhat philosophical comment concerning model experiments. I think that I agree with Dr. Charney's suggestion that machines are suitable for replacing model experiments. But I think it is also necessary to remember that there are in general two types of physical systems which one can think of modeling. In one type of system one has a fairly good understanding of the dynamical workings of the system, involved. Under those conditions the machine modeling is not only practical but probably is more economical in a long run. Typical examples of this kind, I think, are problems where you are concerned, let's say, with wave action in harbors, in general a whole class of engineering problems of that kind. But there is another class of problem where we are still far from a good understanding of the dynamical properties of the system. In that case laboratory models, I think, are very effective and have a very important place in the scheme of things.

PROCEEDINGS  
OF  
THE INTERNATIONAL SYMPOSIUM  
ON NUMERICAL WEATHER  
PREDICTION IN TOKYO ✓  
NOVEMBER 7-13, 1960 ✓

Because of the various simplifications of the model described above, it is not advisable to take too seriously the quantitative aspect of the results obtained in this study. Nevertheless, it is hoped that this study not only emphasizes some of the important mechanisms which control the response of the climate to the change of carbon dioxide, but also identifies the various requirements that have to be satisfied for the study of climate sensitivity with a general circulation model.

(Manuscript received 6 June 1974, in revised form 8 August 1974)

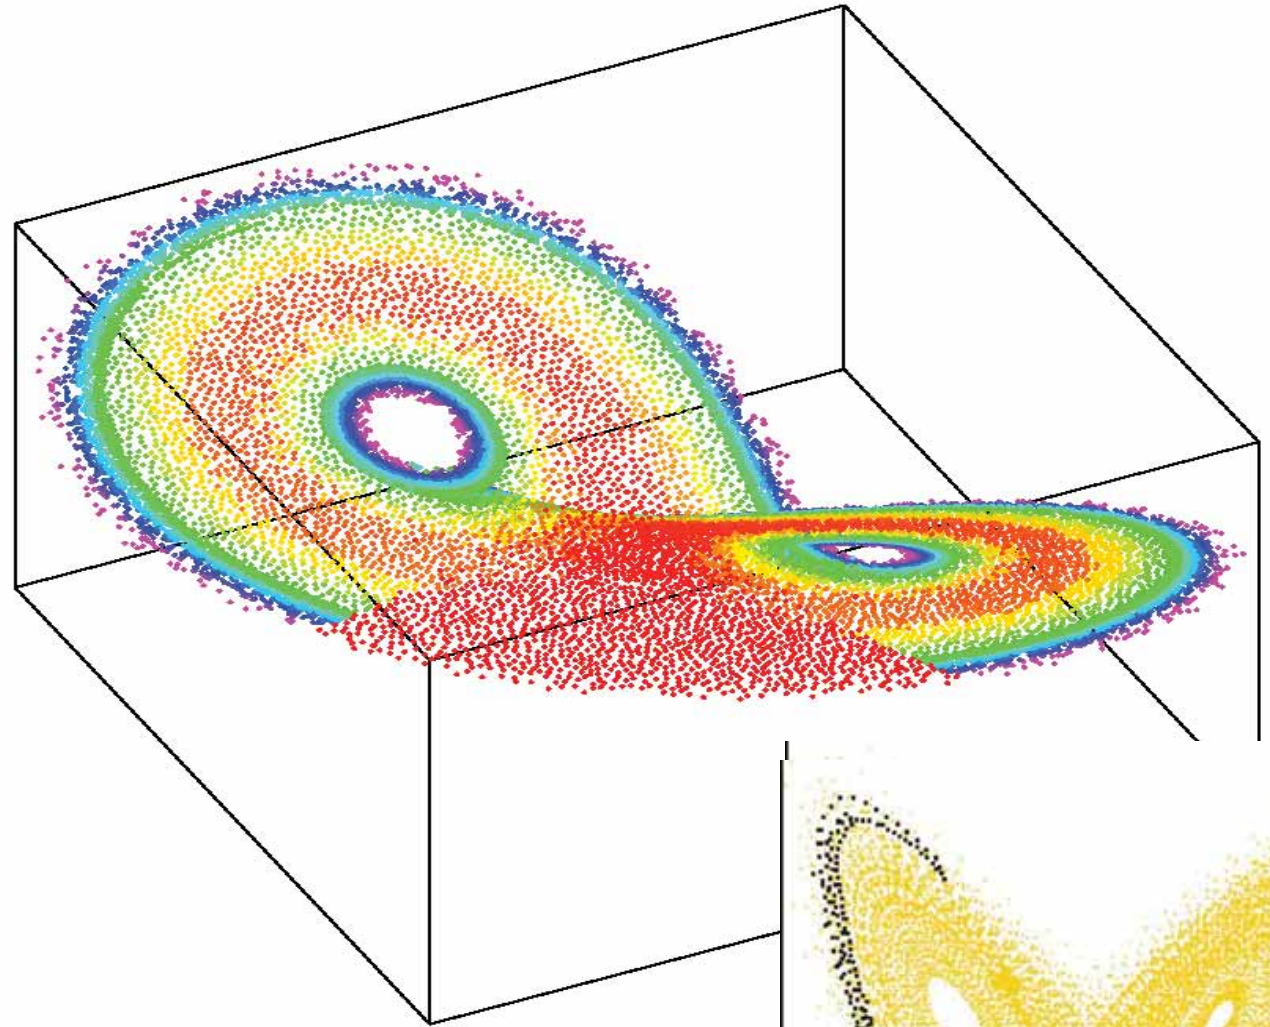

# Ed Lorenz: Weather and Chaos (and Error)

Lorenz realised that even for the Apprentice, small uncertainties could grow exponentially fast, leading to “chaos.”

He was also very concerned about the role of model error, which is much harder to solve than that of mere chaos.

# Probability Forecasts: Chaos

The evolution of this probability distribution for the chaotic Lorenz 1963 system tells us all we can know of the future, given what we know now.

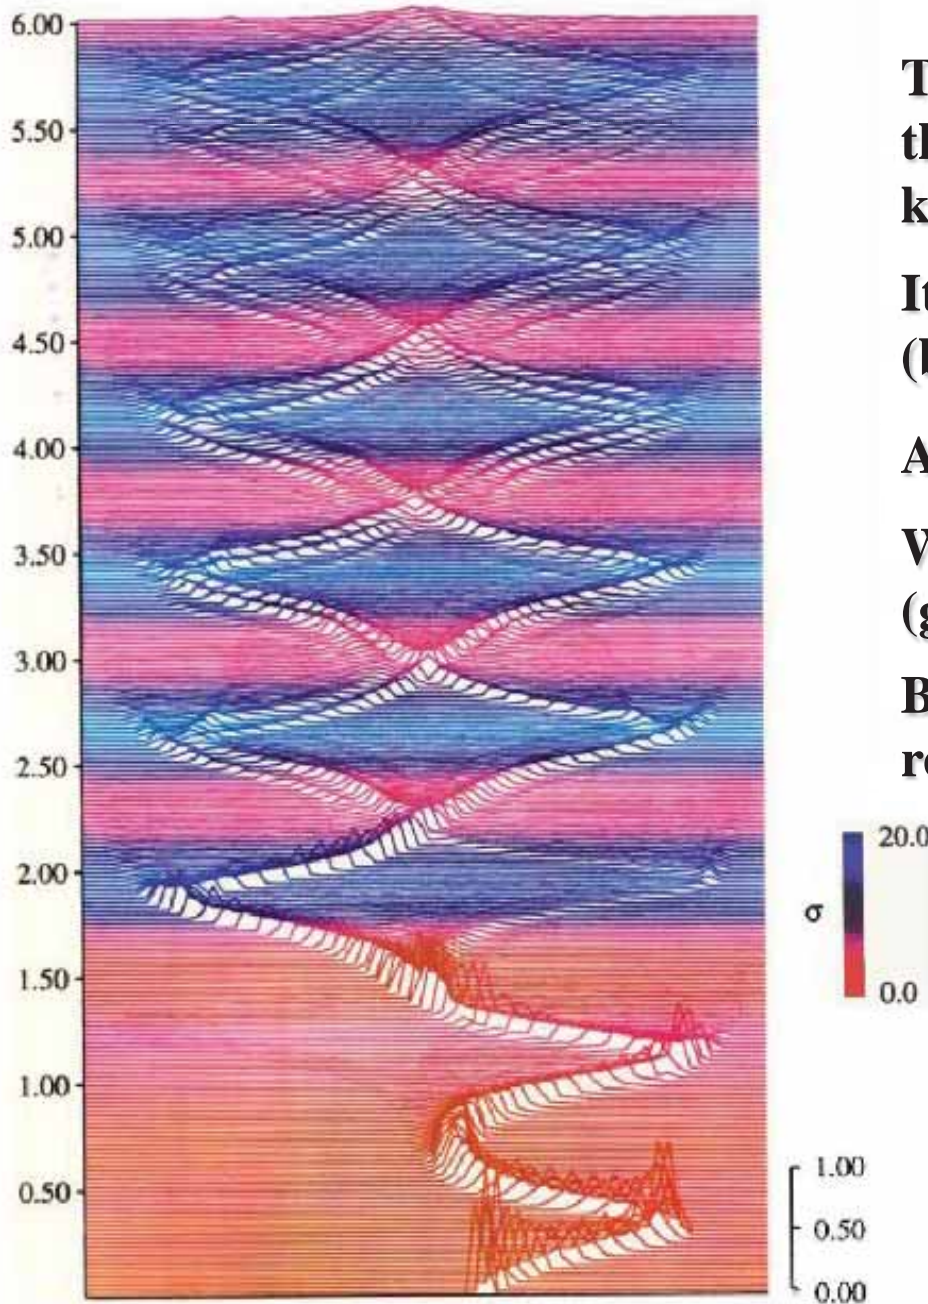

It allows prudent quantitative risk management (by brain-dead risk managers)

And sensible resource allocation.

We can manage uncertainty for chaotic systems (given a perfect model).

But how well do we manage uncertainty in the real world? For GDP? Weather? Climate?

Do we have a single example of a nontrivial system where anyone has succeeded (and willing to offer odds given their model-based PDFs?)

Smith (2002) Chaos and Predictability in *Encyc Atmos Sci*
