

## How to think about Culture in relation to Economic Development

Margaret C. Jacob

When we think about culture in relationship to economic development obviously most historians turn to science and technology as the key elements they wish to better understand. Commonly we think that we know what is meant by the terms, “science” and “technology.” Therein lies the first difficulty. The content and style of both in the past differed markedly from what we may recognize in the present. Not least, their interrelationship also varied considerably from what we think of today. When looking at the critically important eighteenth century we are also looking at the moment when civil engineering was being invented as a distinct discipline. Most practitioners of what we today would confidently describe as engineering - James Watt, John Smeaton, William Jessop for example - saw themselves as “men of science,” or as natural philosophers. They were skilled within the Newtonian educational tradition that became the dominant paradigm for both mechanics and dynamics by 1720 in Britain (by the 1750s in France).

In Newtonian textbook after textbook, in lecture and demonstration - from Francis Hauksbee and Jean Desaguliers in Newton’s lifetime (d. 1727) to John Dalton lecturing in Manchester in 1805 - the subjects addressed began with atomic theory, the relationship between matter and motion, the nature and meaning of the vacuum, and then proceeded by the use of levers, weights and pulleys to illustrate Newton’s three laws, then to explicate mechanics, hydrostatics, hydrodynamics, the nature of steam and the working of machines in general.<sup>1</sup> As early as 1705 experimental

---

<sup>1</sup> For a list of Dalton’s lectures see Arnold Thackray, *John Dalton. Critical Assessments of His Life and Science*, Cambridge, MA, Harvard University Press, 1972, pp.108-12 which in

demonstrators advertised events where instruments were used “to prove the Weight and Elasticity of the Air, its Pressure or Gravitation of Fluids upon each other: Also the new Doctrine of Lights and Colours, and several other matters relating to the same Subjects.”<sup>2</sup> In the 1730s John Grundy a land-surveyor and teacher of mathematics, proposed that every engineer should “understand Natural Philosophy in order to make his Enquiries just.”<sup>3</sup> Shortly thereafter, Desaguliers declared in his *Course of Experimental Philosophy* that philosophers were actually the only realistic guardians to prevent investors from being “impos’d upon by Engine-makers, that pretend to (and often fancy they can) by some new invented Engine out-do all others.”<sup>4</sup> When the profession of civil engineering received cohesion, in 1793 the newly founded Society of Civil Engineers possessed three “classes:” the first “consist of Engineers...actually employed in surveying, designing, and forming works,” the second “consist of Gentlemen...conversant in the Theory or Practice, of the several Branches of Science, necessary...to the civil engineer,” the third, “artists whose professions or employments are necessary and useful to...civil engineering.”<sup>5</sup> Five of the eight gentlemen

---

1805 were as follows: 1 & 2. On matter, motion and mechanic principles, 3. Hydrostatics, 4. and 5. Pneumatics, 6. Hydraulic and pneumatic instruments, 7. 8. & 9. Electricity and Galvinism, 10. Magnetism, 11 & 12. Optics, 13. & 14. On heat, 15. On the elements of bodies and their composition, 16. On mixed elastic fluids and the atmosphere, etc., ending with astronomy, the solar system, eclipses, laws of motion of the planets explained by the whirling table, tides, system of the universe.

<sup>2</sup> *Daily Courant*, Thursday, 11 January 1705, advertising the lectures and demonstrations of James Hodgson, and cited in Larry Stewart, “Science and the Eighteenth-century Public,” in Martin Fitzpatrick, Peter Jones, Christa Knellwolf and Iain McCalman, eds, *The Enlightenment World*, New York, Routledge, 2004, p. 238.

<sup>5</sup> *Rules and Regulations of the Society of Civil-Engineers, London, instituted For promoting and communicating every Branch of Knowledge, useful or necessary, to the various important Works, in Civil-Engineering, April, MDCC, XCIII*. The founding artists were a

were Fellows of the Royal Society (as was Watt, Rennie and Mylne in the first class).

These engineers, gentlemen and practitioners participated in, and helped to fashion, a distinctive scientific culture that effected a union between theory and practice. The Newtonian style as it emerged first in Britain can best be understood comparatively, when seen in relationship to how and what was being taught in science and technology at the same time, for example, in France. When being comparative it helps to walk the multi-lingual terrain with the cultural agents, with scientific practitioners and industrial entrepreneurs. When trying to understand what all of this might have had to do with economic development, it helps to know what contemporaries said about what had to be done, how best to use the science of the day to accomplish profit and growth.

Being comparative in a global age suggests that East and West can be comfortably invoked. Thus Kenneth Pomeranz in his magisterial *The Great Divergence* (2000) tells us that while steam engines were important in the British Industrial Revolution, the Chinese had them too. They knew about atmospheric pressure and - witness their box-bellows - “had mastered a piston/cylinder system much like Watt’s.” In his account China becomes as likely a site “for a series of linked developments in coal and steam central to the Industrial Revolution (p. 62)” as was Britain. Perhaps without realizing it, Pomeranz displays an understanding of technology that sees it as tacit knowledge, the work of trial and error, brilliant tinkering if you like, thus a set of practices largely divorced from a knowledge base. This view is shared by some historians of technology (for example, Ferguson, *Engineering and the Mind’s Eye*, 1992.) Unfortunately the tinkering motif is burdened by our

---

geographer, instrument maker who was FRS, land surveyor, millwright, engine maker, and printer. Joseph Priestley was in the second class as was Charles Hutton.

contemporary division of academic labour between the history of science and history of technology. So specialized, we fail to see how intertwined science and technology were in the 18<sup>th</sup> century, and hence we miss the nature of the scientific culture at work in northern and western Europe throughout much of the early modern period.

The tinkering school in the history of technology would have the execution of machinery be more a matter of practice than of thought. But that is a false dichotomy, at least for the eighteenth and early nineteenth centuries in Britain. In that world, to use our presentist categories, “technologists” were communicating with “non-technologists,” many of them men of science.<sup>6</sup> In other words I am arguing that in their “human built world,” to borrow a phrase from Thomas Hughes, creativity and the ability to “read” the machine depended upon a set of shared skills that industrial entrepreneurs, however technical their manufacturing applications, could own and utilize (in different ways to be sure), along with their scientific cousins (even ones safely arm-chaired in London).<sup>7</sup> Having bellows, or knowing that air exerts pressure is different from understanding the relationship between the vacuum and pressure, giving it mathematical expression, and not least, knowing how to apply trigonometry to measuring the depth of a body of water. When in 1796 James Watt wrote out a list of what a steam engineer needed to know, it began with “the Laws of mechanics as a science,” the “laws of hydraulics and hydrostatics,” and ended with “the doctrine of heat and cold.”<sup>8</sup>

---

<sup>6</sup> Here I am somewhat simplifying the approach found in the otherwise wonderful essay by Steven Lubar, “Representation and Power,” *Technology and Culture*, supplement to April 1995, vol. 36, pp. S53-81. The word “scientist” only became common in the 1830s.

<sup>8</sup> Eric Robinson and A.E. Musson, *James Watt and the Steam Revolution. A Documentary History*, London, Adams and Dart, 1969, pp. 204-05 which prints the manuscript entitled,

Let me give another example of what I mean by the distinctive interface between science and technology. Take the Great Exhibition held in London in 1851. Its process of assessing machinery and reassembling it can be used specifically to discover how science and technology interacted in the presentation of industrial equipment.<sup>9</sup> Dismantled, the machines were sent by industrialists to London, and reassembled for display by a committee of gentlemen, the majority of whom were Fellows of the Royal Society. Those who would sharply separate science from technology might find odd the role played by FRS committee members. Given what we know about the scientific culture at work in the entrepreneurial lives of those who sent the equipment, most of them would have found the interaction to be expected. At the exhibition it might be said that we find “pure technology” removed from its social and economic setting. None of those who reassembled it were inventors, many had probably never been on a factory floor. To be sure, they had help from drawings sent along, and sometimes they had to write back to the entrepreneurs for guidance. Indeed the entire purpose of this exhibition of unprecedented size was to show the world the depth and breadth of British industrial development. It also aimed to “exhibit the beautiful results which have been derived from the study of science.”<sup>10</sup> To the mind of the organizers, the exhibition displayed the achievements of

<sup>10</sup> *The Art Journal. Illustrated Catalogue. The Industry of All Nations*, London, George Virtue, 1851, p. I.

science. It “discovers the laws of power, motion, and transformation,” and the exhibits showcased how “industry applies them to the raw matter which the earth yields us in abundance.”<sup>11</sup> Industrialists sent their machines with descriptions, but the actual working of the devices had to be replicated on the floor of the exhibition and also clearly explained in the massive three volume catalogue that accompanied the show. “The occasion called for a large amount of peculiar knowledge - knowledge not to be gained by study, but taught by industrial experience, in addition to that higher knowledge, the teaching of natural and experimental philosophy.”<sup>12</sup> The marriage between science and industry conceived by Bacon, put into practice by the scientific lecturers of the eighteenth century, and actualized in the factories of men like Watt and Boulton in Birmingham, or M’Connel and Kennedy in Manchester,<sup>13</sup> or the Gotts in Leeds, had become the basis of a credo: the union of hand and head make innovation possible.

The catalogue’s proofs and the text itself were written and corrected by a committee of “scientific gentlemen.” In some cases the proofs were sent out all over the country, back to the owners of the equipment to make sure that the gentlemen had gotten it right. The spirit of Bacon and Robert Boyle was invoked: the need for the natural philosopher to have insight into the trades. The committee made “an attempt...to convert the changing and inaccurate conventional terms of trade into the precise and enduring

expressions of science.”<sup>14</sup> Clearly the interface between science and manufacturing was sufficiently close in the mid-nineteenth century that the scientifically educated, and presumably innovative, could understand industrial devices enough to explain them to the general public. The Exhibition proclaimed: Science works, and combined with the experience that only hands-on labour could give, both made an Industrial Revolution happen. In 1851 the exhibition was used to suggest that the British way of private, local initiatives and dedication to practical science would forever trump all competitors.

But that was in 1851. What would scientifically cultured industrialists and entrepreneurs have said in 1780? Let us look at what they thought to be critically important for success. Here is what in 1784 Watt told a friend whose son wanted to have an industrial career: he needed to know drawing, geometry, algebra, arithmetic and the elements of mechanics. When Watt directed the education of his own son he insisted upon geometry, algebra, “the science of calculation,” physics, mechanics, natural philosophy in general, and bookkeeping.<sup>15</sup> Twenty years earlier when Watt first started his work to improve the steam engine, consistently he spoke about his scientific method, his “experiments,” about their cost, and about how his expenses are part of “my education.”<sup>16</sup> He regularly copied out experiments done by

Transactions*, v. 63, 1991-92, pp. 229-30.

<sup>15</sup> Birmingham City Library, James Watt Papers (hereafter JWP), 6/46, Letter Book, 30 May 1784. By that date his firm alone had installed over 27 engines in Britain. Watt understood the relationship between his science and his industrial success; see same collection, MS3/18, letter of 16 Feb. 1782 Watt to Boulton, “I am certain that with proper loads such an engine can easily make 30 strokes per minute when not impeded by vis inertia or gravity.” On his son’s education see JWP, Letter Book/1 to James Watt, jr, all the letters from the spring of 1785.

<sup>16</sup> JWP 4/59 letters of 1768-1775 (when his patent is secured) to Dr. William Small.

Priestley and La Place into note books where he recorded his own experiments on heat.<sup>17</sup> Experiments on engines at particular cotton mills were also recorded in the same manner.<sup>18</sup> But we might think that Watt was one of a kind.

Acumen in scientific culture was not confined solely to industrialists. At the House of Lords in the 1790s engineers had to justify the digging of new canals through private land. The minutes of the committees reveal that peers of the realm understood enough hydrostatics and hydrodynamics so as to query engineers intensely.<sup>19</sup> To be sure some makers of jennies and spindles were semi-literate, more visual than verbal, but by and large, the creators, installers and users of steam and hydraulic presses, the planners and builders of canals - the key players in the British Industrial Revolution - were mechanically literate and in possession of a distinctive cultural persona. When the leaders of Bristol wanted to restructure its harbour they interviewed the best engineers in the land. They wanted to know the “principles on which the calculations are founded.” William Jessop confessed that as a practical man, like most others, he had forgotten much of his mechanics, and would get back to them in detail. But he enclosed a quick lesson in Galilean or Newtonian laws concerning how by experiment “a heavy body falling from rest will descend about 16 feet in a second of time; and that the velocity acquired...would carry it on in equal time through a sphere of double the height which it fell from, or 32 feet in a second.”<sup>20</sup>

<sup>20</sup>Bristol Record Office, Bright MSS, 11168(3), 15 Nov. 1790, Jessop to Bright.

By the 1780s the choices being made by the entrepreneurs required a specific knowledge and skill base that can be seen in place in Britain, but not yet so clearly - as comparative work has revealed - in France or Belgium.<sup>21</sup> At precisely the same moment Émile Oberkampf, the leading cotton industrialist of Rouen made a set of instructions for his son about what he needed to know to succeed in their business. There is absolutely no mention of mathematics or mechanics.<sup>22</sup> Had the Oberkamps been forced to emigrate in the 1790s they would have had a hard time making a go of it in Manchester. In 1782 Watt criticized one of his competitors in a letter to Boulton, "as his theories are all abstract and run only on the commonly known properties of steam as an elastic fluid I cannot conceive anything wherein he can surpass us particularly as he seems to be greatly divested of geometrical principles."<sup>23</sup> Theorists alone would not do the necessary work, and more than simple arithmetic was also needed.

By the 1780s foreign observers began to realize theory and skill were interconnected. Again at that moment a French industrial spy in Watt's circle, as Watt told Joseph Black, was making "many enquiries about your latent heat."<sup>24</sup> For several decades French ministers of the interior had evinced a growing interest in British technology, an interest that became an obsession by the 1780s. In the wake of revolution the new French makers of educational policy sought to put in place their vision of how science and

technology should interface. It was explicitly modelled on what French observers believed to be the nature of scientific culture in Britain, and what the preponderance of applied science meant for industrial development.

The Napoleonic wars exacerbated the French instinct to compete in market place, factory and classroom. Posters went up in the provinces: *Artistes et mécaniciens de la Gironde!*--search for machines that will replace the hand!<sup>25</sup> As historians of France have put it, "about the turn of the century and on into the early nineteenth century, it became increasingly common for some kind of training in science, in particular in chemistry or the scientific aspects of medicine, to be seen as a natural prelude to entrepreneurial activity."<sup>26</sup> This cultural assumption the British already held dear. By 1820 the French were even obsessively counting all the steam engines in the country, and the overwhelming majority were still imported from Britain.<sup>27</sup> The best scientific minds of the day lectured their readers on the necessity for steam engines, and the government, as well as local societies, awarded prizes for the innovative engines made in France.<sup>28</sup> Also in the provinces new societies were established to study systematically agriculture as well as cotton production - even the weather.<sup>29</sup> Their informal ambience and applied

concerns remind the present-day reader of minutes from the literary and philosophical societies at work across the Channel in places like Manchester. Many of those began in the eighteenth century, but after 1800 fine literature faded from their proceedings, to be replaced by discussions of land cultivation and industrial development. In keeping with the centralization of education, the French societies, unlike their British counterparts, were also charged with finding appropriate students for the new technical schools.<sup>30</sup>

When the French invaded the Low Countries in 1795 a similar effort at industrial development occurred around Brussels and it too was dependent on cotton spinning machines imported from England.<sup>31</sup> In some cases the French even reorganized the faculties of schools aimed at boys aged roughly 14 to 18. The professor of mathematics at Liège, in French-controlled Belgium, taught calculus and trigonometry but now also devoted two months to lessons on terrain and the measurement of elevation for use in maps, while his colleague, also in mathematics, taught arithmetic “relative to commerce and to mathematics, the new system of weights and measures,” and decimalization. In nearby Ghent the professor of chemistry and experimental physics turned the second year of the course in a decidedly applied direction and taught about the properties of water, about thermometers, optics, theory of colours, etc. He then paid considerable attention to the metals that appear in mines, the extraction of minerals, the use of specific gravity to identify substances, and to an examination of the principal substances found in the region. He also gave a course aimed at

commercial students.<sup>32</sup> By 1820 Ghent held an industrial exposition at which its metal industries figured prominently. Because of its cotton industry, it had become known as “Manchester on the Continent.”<sup>33</sup> From recent studies of developing regions and nations we now know that the French promoters of industry and education in applied science, back in the 1790s, had it right: education and knowledge make a difference.<sup>34</sup> Then, however, the French had reason to be worried. Without any of the social scientific evidence we now possess, they turned to the scientific content of their educational curriculum to push it in a more applied direction and thereby to enhance international competitiveness.

Historians a generation ago saw the new French educational system put in place after 1795 - and changed and augmented repeatedly - as an attempt to separate the classes, to keep workers in their place and an “affirmation of the role of the industrial bourgeoisie.”<sup>35</sup> To be sure elements of class dominance were present, yet so too was a new democratic turn. In 1795 the *écoles centrales* had been a democratic experiment that brought general and technical education to a lower level of society where it had never been seen before. In the conservative reaction under Napoleon that experiment was abandoned, and the new, more elite *lycees* replaced the schools. They were meant to favour the sons of military and civil servants as well as serve the industrial needs of the state. Yet very bright students would have their way paid, regardless of what their fathers did for a living. The sites

chosen outside Paris - it would get three of the new schools - were all places where industrial activity already existed.<sup>36</sup>

Rather than seeing the French partnership between industry and the state as a means of social engineering that favoured one class over another, it might better be understood as a somewhat desperate attempt to set up a new innovative class, a scientifically literate meritocracy with entrepreneurial skills that would create the needed institutions. In addition to creating a new nation of republican citizens, and then after the reaction of 1815, a new nation of citizens loyal to their king, the French educational system set out to create a *national*, rather than regional or local, culture receptive to industrial development. The kind of people to be found readily in Manchester must now be created - seemingly out of whole cloth - but from among the children of state functionaries or the exceptionally bright. Report after report focused

---

<sup>36</sup> AN, Roederer MSS 29 AP 75, f.393 a lycee for 150 would have 9 professors and 3 administrators; f. 397 every district to set up its own primary school; directive of 5 April 1802 (f.399) said that mathematics was to be taught in secondary schools. Government will pay for students who are smart enough to secure a place; instruction is to include mathematics, pure and applied, and experimental physics, chemistry, natural history, statistics and technology. There are to be 2 professors of science, one of physics and the other from chemistry; as well as a professor for applied mechanics, *arts et metiers*, and technology. This should all be done by year 11(1803.) The goal is for 6000 students in the lycees, 3000 chosen by the government from the children of military and functionaries "who serve the republic well;" the other 3000 to be chosen by exam. A six year course of study is to be instituted and the government may distribute its largess unequally. Eventually La Fleche and one other of the old colleges is added and 6400 pupils becomes the goal f. 429; "le nombre d'eleves que doit avoir chaque lycee doit varier.." It must be remembered that the state "ne seul qu'une prime pour former les colleges; et ce systeme actual peut eu quelque sorte se comparer au systeme du manufactures, Un Departement n'a-t-il point de manufactures?" After further justifications for why the government should favor manufacturing, the report concludes that by age 15 or 16 the pupils would be nearly finished and doing mechanics and optics (see ff. 645). Professors are to use books approved by the government, and it will consult Delambre and Cuvier at the Institute for advise about the books.

on the equipment needed in these schools, models of machines, chemicals for experiments, new laboratories, the best textbooks.

In Lille, an area already with industrial activity, the local college stressed the need in science to blend theory with practice.<sup>37</sup> In the same town a free course in physics was established by the municipality but encouraged by the national ministry, and in the local secondary school remarkably the professors of letters and physics, as well as design, were paid an equivalent salary.<sup>38</sup> In the new post-1795 school English was also to be taught because it was increasingly the language of commerce.<sup>39</sup> Making good citizens meant in Lille also forming workers who understood the chemical processes in dying and the development of textiles in general.<sup>40</sup>

<sup>43</sup> Jeff Horn and Margaret C. Jacob, “Jean-Antoine Chaptal and the Cultural Roots of French Industrialization,” *Technology and Culture*, vol. 39, 4, 1998, pp. 671-98.

<sup>44</sup> Quoted in Maria M. Portuondo, “Plantation Factories. Science and Technology in Late-

America, see Joyce Appleby, *Inheriting the Revolution. The First Generation of Americans*, Cambridge, MA, Harvard University Press, 2000, p. 59, 108, 113, 115; see also Darwin H. Stapleton, *The Transfer of Early Industrial Technologies to America*, Philadelphia, American Philosophical Society, 2987, pp. 12-31. In the new scientific culture that matured in the eighteenth century, first in Britain then on the Continent, science bled into technique, and both served the cause of technological innovation. Wrapped in the mantle of practical but formal learning, Western industrialists made a place for themselves in towns and cities over which they gradually became economic, then political and cultural leaders.

Such a knowledge base had not always been in place within entrepreneurial circles. In the 1750s a quite prosperous wool spinner and merchant in Leeds - who left a 40 volume personal diary - evinced not a scintilla of scientific knowledge.<sup>45</sup> Within a generation the knowledge and skill possessed by Leeds factory owners had changed. Because of the difficulty of mechanizing wool weaving we do not think of woollen textile manufactures as being at the cutting edge of industrial development. In 1792 the leading woollen and worsted manufacturing firm consulted with Boulton and Watt about installing a remarkable 40 horsepower steam engine, and Benjamin Gott, its most mechanically proficient partner, became a consultant in the region on engineering problems. He also pioneered the use of steam

<sup>45</sup>This example comes from the rediscovery of material that had been in the public domain but ignored; Margaret C. Jacob and Matthew Kadane, "Missing, Now Found in the Eighteenth Century: Weber's Protestant Capitalist," *The American Historical Review*, vol. 108, February 2003, pp. 20-49. See also the trade note book of a clothier, Leeds Record Office, MS GA/B27. A similar transition in educational level can be seen in the post-Civil War American textile industry, "for the postwar world of powered manufacture...sons would need more: an understanding of mechanical principles, capacity to innovate in design, an ability to coordinate production on a grander scale." Quoted from Philip Scranton, "Learning Manufacture: Education and Shop-Floor Schooling in the Family Firm," *Technology and Culture*, vo. 27, 1986, p. 46.

in the process of wool dyeing (weaving mechanically would take many decades to perfect).<sup>46</sup>

Gott also became an expert on a hydro-mechanical press, or Bramah's hydraulic press as it became known, a large and complex piece of equipment introduced late in the century, requiring an understanding of levers, weights and pulleys, air and water pressure and used to imprint patterns on textiles.<sup>47</sup> He carefully compared the relative merits of prototype machines offered by rival manufacturers of the device, but the machine met the fierce opposition of his workers and may never have been systematically used for years.<sup>48</sup> The hydro-mechanical press raised an enormous weight to a small height by using a strong metallic cylinder, accurately bored and made water tight, and it was connected to a small forcing pump.<sup>49</sup> By means of valves, pumps and levers, cisterns and water pressure, 400 pounds of

<sup>46</sup>Brotherton Library, University of Leeds, Gott MS 193/3/f. 98, letter of Davison to Gott asking him if he would go with him to give his opinion of their steam engine to Mr Goodwin... "but if you can't here are queries in writing." Dated 1802 5 May. On the engine and its many uses for scribbling, carding, turning shafts and gearings, stones to grind dyewood see H. Heaton, "Benjamin Gott and the Industrial Revolution in Yorkshire," *The Economic History Review*, vol. 3, 1931-32, pp.52-53. See also John Smail, *Merchants, Markets and Manufacture. The English Wool Textile Industry in the Eighteenth Century*, New York, St. Martin's, 1999, pp. 133-37.

<sup>47</sup>Brotherton Library, MS 193/ 3 f. 94.

<sup>48</sup>Ibid., f. 97 Gott to Bramah from Leeds 29 March 1809 on his hydro-mechanical press: "We have from your letter of the 25<sup>th</sup> instant that the sale and general adoption of your patent presses have been prevented by unfavorable representations respecting the merits & utility of the one you erected for us... we must ...tell you that we look after every operation of the work ourselves, and if we had experienced any advantage from the use of your press, we should have insisted on those men working it, or we should have appointed others in their places who would have been obedient..." See H. Heaton, *op. cit.*, p. 58 who takes a dimmer view of Gott's success in putting the machine to work.

<sup>49</sup>Adrian Randall, *Before the Luddites. Custom, Community and Machinery in the English woollen industry, 1776-1809*, Cambridge, Cambridge University Press, 1991, p. 43. And for the Gott papers see Leeds University Brotherton Library, Special Collections, MS 193/132-192 Benjamin Gott & Sons: Business Letters, 1818-1847, MS 193/32-73 Wormald, Fountaine & Gott: Business Letters, 1792-1795, MS 193/85-88 Wormald, Fountaine & Gott; Miscellaneous Records, 1795-1800, MS 193/74-84, Photostat copies of letters, 1792-96, in Boulton & Watt MSS in Birmingham Public Library.

pressure was accumulated and then released.<sup>50</sup> The press was to be used to apply patterns to worsted just as it had been used in applications to cotton. It called upon just about every principle learned in Newtonian mechanics as taught from Desaguliers to Dalton, and no semi-literate tinkerer in the country could have made sense of it. The knowledge economy advanced in the textbooks, demonstrations and lectures lay embedded in the cotton and wool factories of the 1790s.<sup>51</sup>

The Gott firm and family also became leaders in the civic and industrial life of Leeds. Just like the Boultons and the Watts, the M'Connells and the Kennedys, the Gotts and their local equivalents, the Luptons, Marshalls, Adams and Walkers, established themselves as leaders of a new Philosophical and Literary Society (first chaired by Gott). They and the other seventeen proprietors subscribed 100 for a building to house the society and put out £350 for scientific apparatus.<sup>52</sup> They invited Dalton to be their first lecturer, and not least they commissioned a bust of James Watt intended for display.

In 1821 the opening lecture at the Society valorized the scientific culture here described, and linked it to striving and the industrial order: “the thirst for improvement gives an exaltation of character...produce[s] the works of genius and the discoveries of science...science, no longer confined to the closets of the learned, is applied to the comforts and amelioration of

<sup>50</sup> For a more detailed description see Alexander Tilloch, *The Mechanic's Oracle, and Artisan's Laboratory & Workshop; explaining, in an easy and familiar manner, the general and particular application of practical knowledge, in the different departments of science and art*, London, Caxton Press, 1825, pp. 145-47.

<sup>51</sup> Note that tool making, unlike heat engines, water motors, bridge building, etc received little guidance from scientific principles until the 20<sup>th</sup> century; see Robert B. Gordon, “Who Turned the Mechanical Ideal into Mechanical Reality?,” *Technology and Culture*, October 1988, vol. 29, pp.744-78.

<sup>52</sup> Leeds University, Brotherton Library, Special Collections, MS Dep. 1975/1/6, 7 May 1819.

mankind. Its influence is strikingly apparent alike in our houses and manufactories.”<sup>53</sup> The historical sources, on this occasion left by woolen manufacturers in Leeds, present science and its methods as lying at the heart of a set of values, beliefs, and deployed technological systems, in other words, of a new culture at work in the process of early industrialization. Scientific acumen was not *just* cultural capital, as was once maintained,<sup>54</sup> it was also deployed and woven subtly into the fabric of mechanized factory life.

Culture limits and permits, it does not determine. Only a Hegelian idealist would argue that ideas - or broadly stated culture - set the course of history.<sup>55</sup> In the title of a forthcoming book, Jack Goldstone describes the First Industrial Revolution in the West as “a happy chance.” He sees a fortuitous confluence of economic, political and technological factors that for two or more generations gave Britain a distinct advantage and that led to unprecedented economic growth. It is certainly the case that in 1650 no one in England or Scotland would have predicted the political stability, economic conditions and scientific culture that made the First Industrial Revolution happen. By 1750, at the least, all of those factors were present, and in 1766 we find Josiah Wedgwood writing to a friend, “Many of my experiments turn out to my wishes, and convince me more and more, of the extensive capability of our Manufacture for further improvement...Such a revolution, I believe, is at hand, and you must assist in, [and] profit by it.”<sup>56</sup> If historical

<sup>55</sup> For a theoretical approach to culture and sharing my view of its relationship to economic life see Eric L. Jones, “Culture and its Relationship to Economic Change,” *Journal of Institutional and Theoretical Economics*, vol. 151, June 1995, pp.269-85.

<sup>56</sup> *Letters of Josiah Wedgwood, 1762-1772*, London, 1903, p. 165.

change is random, a gambler's gaze has got to factor in a good hundred years of trends, and avoid making any facile separation of politics from culture, science from technology, and all from economy. Nothing that happened in the cultural life of eighteenth century Britain can be divorced from the relative stability and political liberties put in place decisively in 1688-89. I do not think that culture made the First Industrial Revolution, but I do think that a particular scientific culture had permeated more deeply into British education, formal and informal, than was the case anywhere else on the Continent. I know nothing about China beyond what I read in the work of others. Those experts, when they make comparisons with the European pattern, do need to nuance their understanding of science and technology, to historicize them.

There is another reason for laying emphasis upon scientific culture. Arguably, without securing their social place the first generation of industrial entrepreneurs would have been outliers, in that the knowledge and techniques they had perfected for innovation, particularly in steam and factory, would have remained confined to their businesses and their heirs, and not have become harbingers of a new social and economic order wherein industrialists had to be accommodated politically, and where entrepreneurs quickly came to be envied and imitated. They competed for social leadership with an urban gentry and landed aristocracy whose assumed superiority meant that at the Great Exhibition of 1851 their taste in everything from furniture to spoons was exclusively on display - in the vast wing that complimented the machines. The new industrial entrepreneurs survived not as anomalies, but as exemplars of a new industrial future. They consolidated their social position in town after town by putting their scientific culture to work for them. They set up literary and philosophical societies, mechanics' institutes, museums and exhibitions dedicated to science and

industry. We know that into the 1850s much manufacturing continued to be hand, and not machine or power, although by then everywhere handcraft was threatened by power technology. Also by then a universal recognition existed: what the British, the Belgians, the Swiss, the Americans, more slowly the French and the Dutch, were doing with machinery had to be imitated.
