Nicholas Kaldor 1983, p. 9

However much Ministers may try to revive incentives through tax reductions, they can never hope to achieve the Victorian or Edwardian peaks in fiscal incentives, when income tax was not progressive and it was seven old pence in the pound or 3 percent instead of the present 33 percent. Yet with all those incentives, the economy was stagnating.

Tax Progressivity and Economic Performance

- The debate is not purely academic – it also enters the realm of policy-making.

- Nor is it trivial. Over the last 50 years, it has led to substantial differences across administrations in tax policymaking, with significant distributive implications. For example:

Research Question

What are the economic effects of major tax cuts for the rich?

Previous Work

Previous Work

- Existing macro-level studies mostly provide correlational evidence.

Previous Work

- Existing macro-level studies mostly provide correlational evidence.
- Whilst some studies find that higher tax progressivity is correlated with lower growth (Gemmell et al., 2014), most studies find no significant association (Angelopoulos et al., 2007; Lee and Gordon, 2005; Piketty et al., 2014).

- A number of studies find lower top marginal income tax rates are associated with higher top 1% income shares (Huber et al., 2019; Piketty et al., 2014; Roine et al., 2009).

- We propose a comprehensive approach constructing a new indicator that measures taxes on the rich across countries and over time.
- Bayesian latent variable modelling (Merkle and Rosseel, 2018).
Models were run with normal diffuse priors, three Markov-Chain-Monte-Carlo chains and 1000 burnin iterations.

- Indicators:
 - Top Incomes: Top marginal income tax rates, tax burden on the top 1% of wage earners.
 - Capital: Statutory corporate income tax rate, top marginal tax rate on dividends, effective average tax rate on capital.
 - Assets: Top inheritance tax rate, tax revenue from assets (inheritance/estates/net wealth/immovable property, as % of GDP).

- Threshold often used in empirical literature in macroeconomics (Dell'Erba et al., 2015; Fernández-Villaverde et al., 2015) – but we use 1 standard deviation as an alternative threshold as well.

Empirical Strategy

Empirical Strategy

- Most countries cut taxes on the rich substantially. Hence, focusing on effects of single reforms might be misleading.

- Three main ideas:
 - 1) We compare countries (with similar pre-treatment treatment trajectories) that cut taxes on the rich to those that didn't in a given time period. We repeat this for all major reforms.
 - 2) We calculate the difference-in-differences estimator for different lags and leads. Lags allow us to estimate the development of the effect over time. Leads allow us to check whether the parallel trends assumption holds.
 - 3) We use Mahalanobis distance matching to compare countries with similar covariate trajectories.

Data

- Three main dependent variables:
 - Effects of tax cuts for the rich on inequality (top 1% income shares (Alvaredo et al., 2018))
 - Effects of tax cuts for the rich on economic growth (Real GDP pc in 2011 US Dollars, logged values (Feenstra et al., 2015))
 - Effects of tax cuts for the rich on unemployment (harmonised unemployment rates (OECD, 2020a))
